

DEPARTMENT OF RADIOLOGY

Exam: Chest X-Ray (PA and Lateral)

Date of Exam: November 05, 2026

Patient: Arthur Dent (DOB: 07/11/1955)

Clinical Indication:

71-year-old male presenting with productive cough, fever (102.1 F), and hypoxia. Evaluate for pneumonia.

Technique:

Standard upright PA and Lateral views of the chest were obtained.

Findings:

- Lungs: There is a dense focal consolidation in the right lower lobe with visible air bronchograms. There is also blunting of the right costophrenic angle, consistent with a small to moderate right-sided pleural effusion. The left lung is clear.
- Heart/Mediastinum: The cardiomediastinal silhouette is within normal limits for size and contour. No hilar lymphadenopathy appreciated.
- Bones: Degenerative changes noted in the thoracic spine. No acute displaced rib fractures.

Impression:

1. Right lower lobe consolidation highly suspicious for acute bacterial pneumonia.
2. Associated right-sided pleural effusion.
3. Recommend urgent clinical correlation and initiation of empiric antibiotic therapy. Follow-up imaging in 4-6 weeks to ensure resolution of the consolidation and rule out underlying mass.
